| **Developer** | N. Joshnavi devi | **Team ID** | [Team ID] |
| **Date** | 2 July | **Phase / Document** | Project Demonstration |

## 19. Project Demo Planning

The demo is timed to fit within a typical 10-minute evaluation slot, front-loading the problem context so the live prediction segments are immediately understandable, and reserving the final minutes for questions rather than rushing through them.

| Segment | Duration | Content |
|---|---|---|
| Introduction | 1 min | Problem statement and motivation for a flood-prediction tool |
| Architecture Overview | 2 min | Walkthrough of layered architecture and data flow |
| Live Demo — High Risk Scenario | 2 min | Auto-Fill / enter high-rainfall values, show Severe Flood Warning output |
| Live Demo — Low Risk Scenario | 2 min | Enter low-rainfall values, show Normal Conditions output |
| Model Comparison Recap | 1 min | Summarize train.py accuracy comparison across the four models |
| Q&A | 2 min | Address evaluator questions |

Running both a high-risk and a low-risk scenario back-to-back is a deliberate choice: it is the fastest way to prove, in front of an evaluator, that the severity classification actually responds to changes in input rather than always returning the same tier regardless of what is entered.
