

Project Title	Rising Waters: Machine Learning Based Flood Prediction System		
Developer	S. Ramya Sathwika	Team ID	[Team ID]
Date	26 June	Phase / Document	Brainstorming & Ideation

3. Empathy Map

Persona: Resident / local monitoring authority in a flood-prone region.

The empathy map below was built to keep the design grounded in how this persona actually experiences the problem — not just what data they need, but what they say, think, feel, and do in the run-up to a potential flood event. This is what motivated features such as the Auto-Fill demo generator (so a first-time or non-technical user is never blocked by not knowing exact meteorological figures) and the plain-language insights layer (so the output reads as guidance, not a raw statistic).

EMPATHY MAP

Quadrant	Observations
Says	“Will it flood this season?”, “I need to know before the rain gets worse.”
Thinks	Concerned about safety of property and family; unsure how to interpret raw weather reports.
Does	Checks generic weather apps/news; relies on word-of-mouth or delayed official advisories.
Feels	Anxious, reactive, and underinformed during monsoon season.
Pain Points	No quick way to translate rainfall/humidity data into an actionable risk level; advisories often arrive late.
Gains Expected	Instant, understandable risk classification; clear guidance on what to do next.

Two pain points recur across this map — the delay between data being available and a person understanding what it means, and the lack of a concrete next action once risk is understood. Both are addressed directly in the final product: the former by an instant, on-demand prediction endpoint, and the latter by the severity-tiered safety-protocol list returned alongside every result.
